

Backus-Naur Form (BNF)

• Words in <> are called non-terminals since they

• The symbols < > ::= are called meta-characters

since they are part of the BNF language, not part

Structural Programming and Data Structure

<sentence> ::= <subject> <verb> <article> <adjective> <object>.

is called Backus-Naur Form (BNF).

· All other symbols (like the dot) are called

terminals and must appear as shown.

must be further defined.

of the target language.

• The notation:

Dr. Osmar R. Zaïane, 2000

Tokens and Lexics Alphabetic symbols in many natural languages are combined into words. Alphabetic symbols in programming languages are combined into tokens. The rules for combining alphabetic symbols into tokens is often called lexics. The lexical rules are usually expressed independently from the grammar rules that describe how tokens can be combined into larger syntactic structures.

Variable Declarations

- Every Java variable must be declared.
- The syntax for each kind of variable declaration is different. (static, local, parameter, and instance variable)
- In this lecture, we will ignore instance variable declarations and method parameter declarations since we are not going to use them yet.
- A common approach is to declare each variable using its own declaration statement.

Structural Programming and Data Structure

Static Variable Declarations

- Static variables:
 <stat var dec> ::= <visibility> static [final] <class id> <var id><visibility> ::= public | private
- If the keyword final is included, the variable is actually a constant.
- For example, there is a public variable exported from class System that is bound to the screen and declared by:

Local Variable Declarations

· Local variables:

© Dr. Osmar R. Zaiane, 2000

- <local var dec> ::= [final] <class id> <var id>
- If the keyword final is included, the variable is actually a constant.
- For example, we declare local String and Date variables and a local Date constant:

String myString;

Date aDate;

final Date birthDate;

Variable References

- Variables are used by writing variable references.
- A local variable reference is just the variable name (an identifier).
 <local var ref> ::= <id>
- A static variable reference is: <static var ref> ::= <export class> . <id>

Structural Prog

• For example to refer to the screen object: *System.out*

Import Statements

- An **import** statement must be used to access the classes in a package.
- You can import one class from a package: *import java.util.Date;*
- You can import all classes from a package: import java.util.*;
- One package: **java.lang** is implicitly imported into all Java programs.
- String and System are two classes in the java.lang package.

 Dr. Omer H. Zam. 200
 Succural Programming and Data Structures
 University of Aberts (4)

Static Variable Shortcut

- If a static variable is used inside its exporting class, you can omit the exporting class.
- For example, inside the System class, the screen object can be referenced by: *out*

- If our problem is more complex than sending a few messages, we must decompose the problem into small steps.
- An algorithm is a finite collection of steps, performed in a prescribed order that terminates and yields a correct solution to a problem.
- For now, we will look at algorithms that consist of a simple series of consecutive steps.
- Later in the course, we will study algorithms that perform steps conditionally and repeat steps. University of Alberta Structural Programming and Data Structures

- We can implement the algorithm by putting a sequence of message expression statements and assignment statements into our program template.
- There are four new computations we need to perform:
 - input a String from the keyboard
 - input an Integer from the keyboard
 - pause until the user presses the ENTER key
