# Semi-structured data representation model

- ◆ In OEM, each object contains an object identifier and a value(atomic/complex)
- ◆ Atomic values : intergers, real, strings, images, program.
- ◆ A complex value is a collection of 0 or more OEM sub-objects.

# Example

(semi-structured model)

```
Root complex()
File complex()
Name string "Microsoft Word"
Size string "100"
Avatar of http://Microsoft/Avatar/Avatar-Object
- (1992)
Geo complex()
Keyword string "factor"
Keyword string "Biological"
Keyword string "Micro-Organism"
1
Structure of http://New/Structure/Tree
2
Step/Name/Structure/Tree complex()
Name string "Micro-Organism"
Avatar of http://New/Structure/Avatar/Avatar-Object (1992)
Complex()
Name string "Tree"
3
Step/Name/Structure/Tree/Complex()
Name string "Golden-Globe"
3

- ◆ Schema knowledge discovery for semi-structured data
- ◆ Conclusion

# The implementation of semi-structured data extraction

## ◆ Procedure

- provide an initial http address to semi-structured data extractor
- extractor starts to get the needed HTML file from corresponding remote web server
- store it in OEM model
- if useful hyperlinks are detected, be inserted in a Queue
- After extraction, the semi-structured data can be used for schema knowledge discovery

# Example

(The file used to extract information on film pages on web)

```

1[
2Extract      <TITLE>*/ /*the match pattern*/
3Add label:   Name      /*the label to be added*/
4Num of Value: 1      /*the number of value*/
5]
.....
6[
7Extract:    HREF=""/More?towards+*
8Add label:  Award
9Num of Value: 1
10Page type: 1      /*a hyperlink*/
11]
.....

```

# Algorithm

```

Algorithm f: extract_info()
Input:  Q: Queue to store the http address;
Output: Semi-structured Data Represented by OEM;
{
  Match ← True;
  While (Q≠empty) do {
    addr ← first entry in Q;
    get an HTML document Doc(addr) from remote
    web server;
    read the corresponding tag file Tag(Doc(addr));
    repeat {
      if (Match ← True or Cur_tag ← NIL) then
        S ← the starting position of next string in
        Doc(addr);
        Cur_tag ← Current tag in Tag(Doc(addr));
        if (Cur_tag is the prefix pointed by S) then
          Match ← True;
          P ← Tag(Doc(addr));
          else advance the pointer in Tag(Doc(addr));
          Match ← False;
        until
        (not EOP(Doc(addr)) or EOP(Tag(Doc(addr)))
    } and while
  }
}

```

- P(S, Tag(f)) performs a particular data extraction task
- o. First case
    - The information V followed cur\_tag needs to be extracted. If V is atomic, then add<label, V> to OEM database
    - If V is a hyperlink pointed to another page, then append V and the specification file number for extracting corresponding web pages to the tail of queue Q.
  - o. Second case
    - The algorithm has detected cur\_tag. This means that the contents following cur\_tag in the file have no more values for the current attribute.

# Schema knowledge discovery for semi-structured data

Definition 1

Extension : If object O has n outgoing edges, with  $l_i$  labeled on each edge and ending object  $O_i$

$Ext(O) = \{ \langle l_1, O_1 \rangle, \dots, \langle l_n, O_n \rangle \}$  → a direct extension of O

$Ext(O_{ij}) = \{ \langle l_{i1}, O_{i1} \rangle, \dots, \langle l_{im}, Ext(O_{im}) \rangle \}$  → an extension of  $O_{ij}$

Definition 2

Transaction : If no any object includes  $Ext(T)$  as an element in its extension, then we call  $Ext(T) = \{ \langle l_1, T_1 \rangle, \dots, \langle l_n, T_n \rangle \}$  a transaction.

Definition 3

Frequent K-schema : A K-schema is a generalized extension with K atomic object, I.e. each object has no extension.

# The directional graph representation

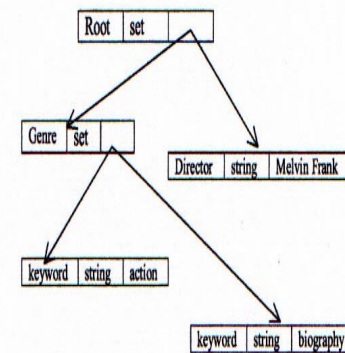

Fig.4 The Directional Graph Representation

- A transaction :  $T = \{ \langle \text{genre, keyset} \rangle, \dots, \langle \text{Director, Melvin Frank} \rangle \}$
- A extension : Keyset is a complex object whose extension is  $Ext(\text{keyset}) = \{ \langle \text{Keyword, action} \rangle, \langle \text{Keyword, biography} \rangle \}$
- Frequent K-schema : generalized extension is  $\{ \langle \text{Genre, } \{ \langle \text{Keyword, Action} \rangle, \langle \text{Keyword, Biographical} \rangle \} \rangle, \langle \text{Director, Melvin Frank} \rangle \}$

# Schema supported by transaction

Two 1-schema

$PT_1 = \{ l_1, \langle l_3, O_4 \rangle \}$

$PT_2 = \{ l_1, l_4, \langle l_5, O_7 \rangle \}$

A 2-schema(Based on  $PT_1, PT_2$ )

$PT_1 PT_2 = \{ l_1, \{ \langle l_3, O_4 \rangle \}, \{ l_4, \langle l_5, O_7 \rangle \} \}$

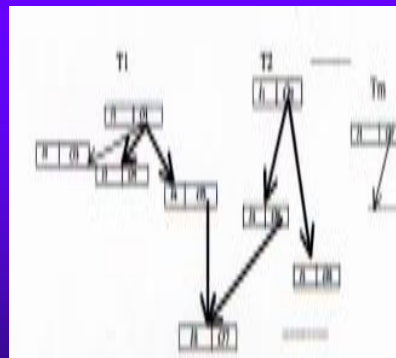

Fig.5 The 2-schema supported by transaction T1 and T2 (those with thick black arrows and the connected nodes)

# Algorithm (Generating K-schema)

```

Algorithm 2: Generating k-schemas)
Input: transaction database;
Output: frequent k-schemas;
1
for each transaction Ext(T) do
  for each descending path PTi = {l1, l2, ..., li}, Oi do
    if PTi is traversed for the first time in Ext(T) then
      ++support(PTi);
  for each PTi do
    if support(PTi) = minsup then
      add PTi = {l1, l2, ..., li}, Oi to PTk;
      store all the nodes {l1, l2, ..., li} associated with PTi;
  for i=2; PTk≠∅; i=i+1 do
    CPTk = generate_candidate_schemas(PTk, i);
    for each transaction Ext(T) do
      for each candidate k-schema s in CPTk do
        if s is structure(s, Ext(T)) then
          ++support(s);
    for each candidate k-schema s in CPTk do
      if support(s) ≥ minsup then
        add s to PTk;
1
output: PT1 ∪ ... ∪ PTk;

- ◆ Schema knowledge discovery for semi-structured data
- ◆ Conclusion

## Conclusion

- With the rapid growth of WWW, the semi-structured data will be richer and richer.
- Two directions will be introduced in the future.
  - Machine learning method to the recognition of tag information in extraction
  - The clustering method in semi-structured data knowledge discovery
